MÉTODOS DE COMPUTACIÓN ESTADÍSTICA

Chapter 1

Introduction to MATLAB

1.38. The classic quadratic formula says that the two roots of the quadratic equa−

tion

$ax2 + bx + c = 0$

are

$x1; x2 = ¡b \S pb2 ¡ 4ac$

$2a$

Use this formula in Matlab to compute both roots for

$a = 1; b = ¡100000000; c = 1$

Compare your computed results with

roots([a b c])

What happens if you try to compute the roots by hand or with a hand

calculator?

You should ¯nd that the classic formula is good for computing one root, but

not the other. So use it to compute one root accurately and then use the fact

that

$x1x2 = c$

a

to compute the other.

X1=(−10^−8+sqrt(10^16−4))/2

X1 =

5.0000e+007

X2=(−10^−8−sqrt(10^16−4))/2

X2 =

−50000000

>> help roots

roots([1 10^8 1])

ans =

−0.0000

Ejercicio sin número sobre error absoluto y error relativo:

Calcular el error absoluto y relativo producido al calcular n factorial con la formula de Stirling n=1,..,17.

f=factorial(10)

f =

3628800

>> fs=sqrt(2*pi*10)*exp(−10)*(10^10)

fs =

3.598695618741036e+006

>> er=abs(f−fs)/f

er =

0.00829596044394

ea=abs(f−fs)

ea =

3.010438125896407e+004

f=factorial(20)

f =

2.432902008176640e+018

>> fs=sqrt(2*pi*20)*exp(−20)*(20^20)

```
fs =

2.422786846761134e+018

>> ea=abs(f−fs)

ea =

1.011516141550643e+016

>> er=abs(f−fs)/f

er =

0.00415765262288
```

Ejercicio sin numero:

```
% error relativo y absoluto

%en la formula de Stirling

%imprime una tabla mostrando

%el error producido por la

%aproximacion de Stirling

%para n!

close all;clc

disp('')

disp(' Aproximation absolute relative')

disp(' n n! Stirling error error')

disp('−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−

e=exp(1);

nfact=1;

for n=1:17

%f=factorial(n);

f=n*f;

fs=sqrt(2*pi*n)*((n/e)^n);
```

abserror=abs(f−fs);

relerror=abserror/f;

d=sprintf(' %2.0f %16.0f %18.2f %16.2f %5.2e',...

n,f,fs,abserror,relerror);

IMPORTANTE:%18.2 es 18 digitos con 2decimales,por lo tanto quedan 16enteros;la f sigifica el formato que le corresponda y la e significa en formato decimal;como d=sprintf(' %2.0f %16.0f %18.2f %16.2f %5.2e',...

n,f,fs,abserror,relerror) esta entre comillas eso significa que es un texto

disp(d)

end

Lo compruebo o ejecuto:

Aproximation absolute relative

n n! Stirling error error

MATLAB respuestas a la pagina 49 de unidades didácticas 01_intro.pdf

```
%este programa calcula el
%seno de x usando el
%desarrollo en serie de taylor
%en torno al cero
%sin(x) = x − x^3/3! + x^5/5! − ...
%el criterio de parada del
%bucle "while" consiste en
%que el siguiente termino
%de la serie sea tan pequeño
%que no modifique el resultado
%obtenido hasta el momento
function s = powersin(x)
s = 0;
t = x,
n = 1;
while s + t ~= s;
s = s+t;
t = − x.^2/((n+1)*(n+2)).*t *para hallar ~ es: alt+126
n = n+2;
end
```

- *control+c desbloquea las operaciones*

lo abrimos y lo usamos:

>> powersin(pi)

t =

3.1416

ans =

2.4791e−016

>> x = 11*(pi)/2;

>> e=abs(powersin(x)−1)

t =

17.2788

e =

2.0000

>> sin(11*pi/2)

ans =

−1

>> sin(21*pi/2)

ans =

1

>> e = abs(powersin(x)+1)

t =

17.2788

e =

2.1287e−010

**donde e es igual al erros, abs igual al valor absoluto.*

>> x = 21*(pi)/2;

```
>> e = abs(powersin(x)+1)

t =

32.9867

e =

1.9999

>> e = abs(powersin(x)−1)

t =

32.9867

e =

1.3324e−004

>> x = 31*(pi)/2;

>> e = abs(powersin(x)−1)

t =

48.6947

e =

5.8230e+003
```

- modificamos el programa inicial:

```
function [s,k] = powersin(x)

s = 0;

t = x,

n = 1;

k = 0;

while s + t ~= s;

k = k +1;

s = s+t;

t = − x.^2/((n+1)*(n+2)).*t;
```

```
n = n+2;

end
```

Operamos:

```
>> [s,k]= powersin(x)

t =

48.6947

s =

−5.8220e+003

k =

78

>> x = (pi)/2;

>> [s,k]= powersin(x)

t =

1.5708

s =

1.0000

k =

11
```

*cambiamos de nuevo el programa :

```
function [s,k,tmax] = powersin(x)

s = 0;

t = x,

n = 1;

k = 0;

tmax=x;

while s + t ~= s;
```

```
k = k +1;

s = s+t;

t = − x.^2/((n+1)*(n+2)).*t;

if t > tmax

tmax = t;

end

n = n+2;

end
```

operamos:

```
>> x = (pi)/2;

>> [s,k,tmax]= powersin(x)

t =

1.5708

s =

1.0000

k =

11

tmax =

1.5708

>>

>> x = 11*(pi)/2;

>> [s,k,tmax]= powersin(x)

t =

17.2788

s =

−1.0000
```

k =

37

tmax =

3.0665e+006

Modificando de nuevo:

```
function [s,k,tmax,t] = powersin(x)

s = 0;

t = x,

n = 1;

k = 0;

tmax=x;

while s + t ~= s;

k = k +1;

s = s+t;

t = − x.^2/((n+1)*(n+2)).*t;

if t > tmax

tmax = t;

end

n = n+2;

end
```

Operamos

```
>> [s,k,tmax,t]= powersin(x)
```

t =

17.2788

s =

−1.0000

k =

37

tmax =

3.0665e+006

t =

−2.6232e−017

>>

Pasamos al ejemplo 2.11 del libro de moler capitulo 002 pagina 37.

2.7 lutx, bslashtx, lugui

We have three functions implementing the algorithms discussed in this chapter.

The ¯rst function, lutx, is a readable version of the built−in Matlab function lu.

There is one outer for loop on k that counts the elimination steps. The inner loops

on i and j are implemented with vector and matrix operations, so that the overall

function is reasonably e±cient.

```
function [L,U,p] = lutx(A)
%LU Triangular factorization
% [L,U,p] = lutx(A) produces a unit lower triangular
% matrix L, an upper triangular matrix U, and a
% permutation vector p, so that L*U = A(p,:).
[n,n] = size(A);
p = (1:n)'
```

```
for k = 1:n−1
% Find largest element below diagonal in k−th column
[r,m] = max(abs(A(k:n,k)));
m = m+k−1;
% Skip elimination if column is zero
if (A(m,k) ~= 0)
% Swap pivot row
if (m ~= k)
A([k m],:) = A([m k],:);
p([k m]) = p([m k]);
end
% Compute multipliers
i = k+1:n;
A(i,k) = A(i,k)/A(k,k);
% Update the remainder of the matrix
j = k+1:n;
A(i,j) = A(i,j) − A(i,k)*A(k,j);
end
end
% Separate result
L = tril(A,−1) + eye(n,n);
U = triu(A);
```

Y la versión simplificada de este operador la llama: Bslashtx(A,b) [backslash]:

```
function x = bslashtx(A,b)
% BSLASHTX Solve linear system (backslash)
% x = bslashtx(A,b) solves A*x = b
```

```
[n,n] = size(A);
if isequal(triu(A,1),zeros(n,n))
% Lower triangular
x = forward(A,b);
return
elseif isequal(tril(A,−1),zeros(n,n))
% Upper triangular
x = backsubs(A,b);
return
elseif isequal(A,A')
[R,fail] = chol(A);
if ~fail
% Positive definite
y = forward(R',b);
x = backsubs(R,y);
return
end
end
```

Realizamos otro programa para la inversa (ejercicio 2.11 de moler)

```
%Ejercicio 2.11 del libro de Moler
%este programa nos permite calcular
%la matriz inversa de una matriz
%usando la factorización LU y
%las versiones sencillas de los
%programas LU y \ que nos ofrece
%el libro de Moler
```

```
function X = miinversa(A)
[n,n] = size (A);
E = eye(n);
for i=1:n
%x(:,i)=bslashtx(A,E(:,i));
X(:,i)= A\E(:,i);
end
```

aplicamos en matlab:

```
A =
0 1
1 0
>> miinversa(A)
ans =
0 1
1 0
>> B=rand(50);
>> X=miinversa(B);
>> norm(B*X − eye(50))
ans =
2.3934e−014
>> X2=inv(B);
>>
>> norm(B*X2 − eye(50))
ans =
1.2760e−013
>> cond(B)
```

ans =

517.6219

>> plot(X,Y,'r*',u,v)

u=0:0.01:4;

>> v= 6 −5.5*u+315*u.^2;

(es el polinomio obtenido antes evaluado en los puntos dados)

>> plot(X,Y,'r*',u,v)

Y obtenemos:

*Tenemos los siguientes programas:

```
function v = polyinterp(x,y,u)
%POLYINTERP Polynomial interpolation.
% v = POLYINTERP(x,y,u) computes v(j) = P(u(j)) where P is the
% polynomial of degree d = length(x)−1 with P(x(i)) = y(i).
% Use Lagrangian representation.
% Evaluate at all elements of u simultaneously.
n = length(x);
v = zeros(size(u));
for k = 1:n
w = ones(size(u));
for j = [1:k−1 k+1:n]
w = (u−x(j))./(x(k)−x(j)).*w;
end
v = v + w*y(k);
end
```

número de puntos

Y:

```
function v = piecelin(x,y,u)
%PIECELIN Piecewise linear interpolation.
% v = piecelin(x,y,u) finds the piecewise linear L(x)
% with L(x(j)) = y(j) and returns v(k) = L(u(k)).
% First divided difference
delta = diff(y)./diff(x);
% Find subinterval indices k so that x(k) <= u < x(k+1)
n = length(x);
k = ones(size(u));
for j = 2:n−1
k(x(j) <= u) = j;
end
% Evaluate interpolant
s = u − x(k);
v = y(k) + s.*delta(k);

Del capitulo 3pdf la segunda parte.

$$P(x) = \frac{3hs^2 - 2s^3}{h^3} y_{k+1} + \frac{h^3 - 3hs^2 + 2s^3}{h^3} y_k + \frac{s^2(s-h)}{h^2} d_{k+1} + \frac{s(s-h)^2}{h^2} d_k$$

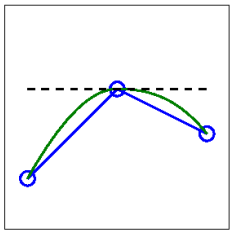
pchip

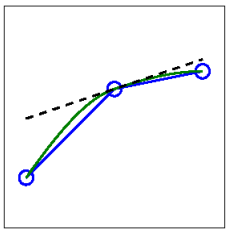
If δ_k and δ_{k-1} have opposite signs

$$d_k = 0$$

else

$$\frac{1}{d_k} = \frac{1}{2}\left(\frac{1}{\delta_{k-1}} + \frac{1}{\delta_k}\right)$$





Local power form

$$P(x) = y_k + sd_k + s^2c_k + s^3b_k$$

$$\begin{aligned} c_k &= \frac{3\delta_k - 2d_k - d_{k+1}}{h} \\ b_k &= \frac{d_k - 2\delta_k + d_{k+1}}{h^2} \end{aligned}$$

- Este es un buen método (el pichip) para interpolar, pero los hay mejores(el splines)

*Los ptos di son knots

K=1 d0+4d1+d3 = 3 +3 eliminada

K=2 d1+4d2+d4=3 +3

K=3 d2+4d3+d5=3 +3

K=4 d1+4d4+d6=3 +3

K=5 d4+4d5+ d7=3 +3 eliminada

.−Si esto no funciona usamos spline, de la cual una versión simplificada es la splinetx.m , que es:

```
function v = splinetx(x,y,u)

%SPLINETX Textbook spline function.

% v = splinetx(x,y,u) finds the piecewise cubic interpolatory

% spline S(x), with S(x(j)) = y(j), and returns v(k) = S(u(k)).

%

% See SPLINE, PCHIPTX.

% First derivatives

h = diff(x);

delta = diff(y)./h;

d = splineslopes(h,delta);

% Piecewise polynomial coefficients

n = length(x);

c = (3*delta − 2*d(1:n−1) − d(2:n))./h;

b = (d(1:n−1) − 2*delta + d(2:n))./h.^2;

% Find subinterval indices k so that x(k) <= u < x(k+1)

k = ones(size(u));

for j = 2:n−1

k(x(j) <= u) = j;

end

% Evaluate spline

s = u − x(k);

v = y(k) + s.*(d(k) + s.*(c(k) + s.*b(k)));
```

Ensaya las primeras derivadas

* Implementa alguno de los métodos para hallar las di. (not−a kan ; loked)

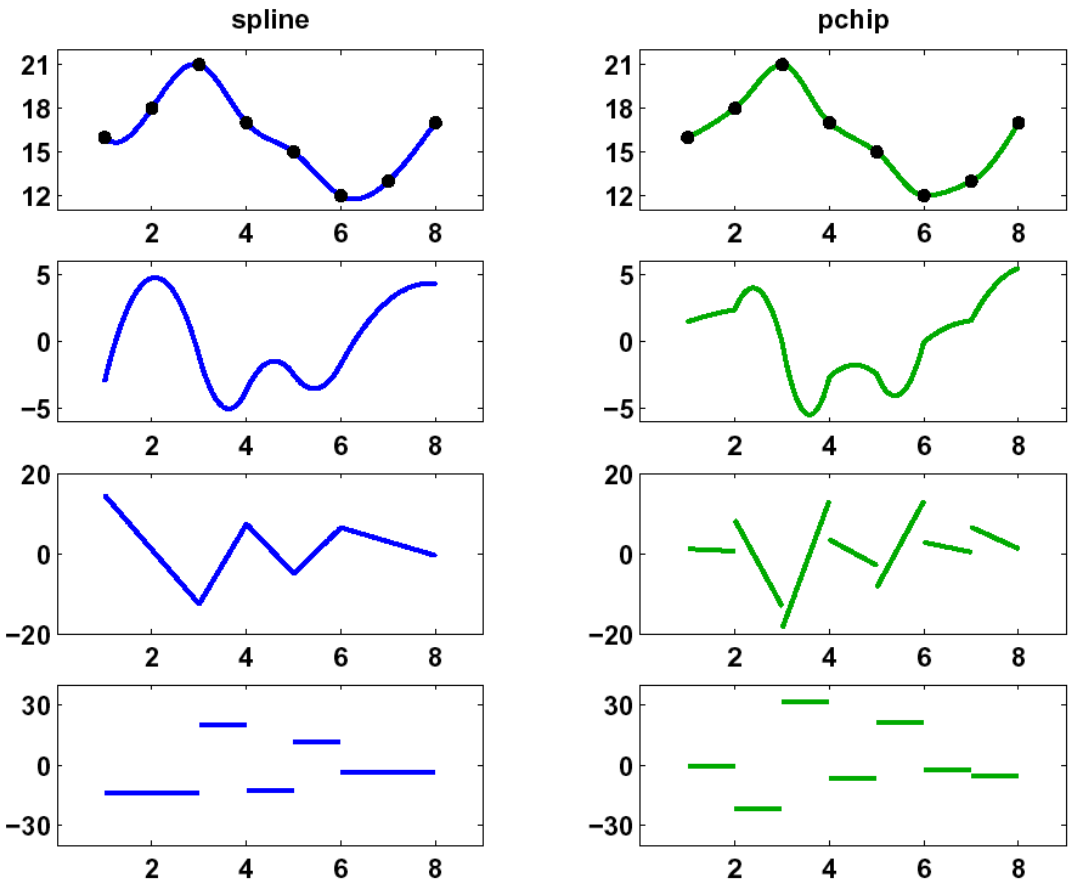
De momento esto lo olvidamos

P(x) = s, es el output.

*para ordenar los puntos de manera creciente, en matlab usamos el comando sort.

Por ejemplo si tenemos un vector X usamos un comando Y=sort(x), nos aparece un vector ordenado de menor a mayor.

miramos del capitulo 3:



Donde gráficamente reconocemos si una función es o no derivable por las propiedades estudiadas en cálculo.

Seguimos usando el programa splinetx.m y aplicamos en matlab.

*el punto antes de una operación significa, componente a componente.

También usamos el programa splineslopes:

function d = splineslopes(h,delta)

% SPLINESLOPES Slopes for cubic spline interpolation.

% splineslopes(h,delta) computes d(k) = S'(x(k)).

% Uses not−a−knot end conditions.

% Diagonals of tridiagonal system

```
n = length(h)+1;

a = zeros(size(h)); b = a; c = a; r = a;

a(1:n−2) = h(2:n−1);

a(n−1) = h(n−2)+h(n−1);

b(1) = h(2);

b(2:n−1) = 2*(h(2:n−1)+h(1:n−2));

b(n) = h(n−2);

c(1) = h(1)+h(2);

c(2:n−1) = h(1:n−2);

% Right−hand side

r(1) = ((h(1)+2*c(1))*h(2)*delta(1)+h(1)^2*delta(2))/c(1);

r(2:n−1) = 3*(h(2:n−1).*delta(1:n−2)+h(1:n−2).*delta(2:n−1));

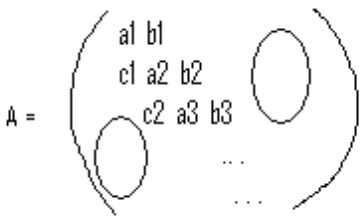
r(n) = (h(n−1)^2*delta(n−2)+(2*a(n−1)+h(n−1))*h(n−2)*delta(n−1))/a(n−1);

% Solve tridiagonal linear system

d = tridisolve(a,b,c,r);
```

Usa una matriz tri−diagonal (con tres diagonales) y se soluciona gracias a tridisolve

Tridiagonal:



Trisolve(a,b,c,r)

Ax = r

x = A \ r

las condiciones descritas en nuestro ejemplo not−a−knot

$$A = \begin{pmatrix} h_2 & h_2+h_1 & & & \\ h_2 & 2(h_2+h_1) & h_1 & & \\ & \cdots & \cdots & \cdots & \\ & & h_{n-1} & 2(h_{n-1}+h_{n-2}) & h_{n-2} \\ & & & h_{n-1}+h_{n-2} & h_{n-2} \end{pmatrix}$$

Para la primera ecuación: h2d1+h2+a1d2 = = (hn−1+hn−2)dn−1+hn−2*dn=

Del capitulo 3 del libro de Mooler, página 22 :

3.11. Modify splinetx and pchiptx so that, if called with two output arguments,

they produce both the value of the interpolant and its ¯rst derivative. That

is,

[v,vprime] = pchiptx(x,y,u)

and

[v,vprime] = splinetx(x,y,u)

compute *P*(*u*) and *P0*(*u*).

[v,v1,v2,v3] = splintex4(x,y,n)

Creamos un nuevo programa a partir del splintex:

%Este programa resuelve el problema 3.11

% del libro de mooler(modificado)

function [v,v1,v2,v3] = splinetx3(x,y,u)

%SPLINETX Textbook spline function.

% v = splinetx(x,y,u) finds the piecewise cubic interpolatory

% spline S(x), with S(x(j)) = y(j), and returns v(k) = S(u(k)).

% and the first, second and third derivatives

%v1 , v2, v3.

% See SPLINE, PCHIPTX.

% First derivatives

h = diff(x);

delta = diff(y)./h;

```
d = splineslopes(h,delta);

% Piecewise polynomial coefficients

n = length(x);

c = (3*delta − 2*d(1:n−1) − d(2:n))./h;

b = (d(1:n−1) − 2*delta + d(2:n))./h.^2;

% Find subinterval indices k so that x(k) <= u < x(k+1)

k = ones(size(u));

for j = 2:n−1

k(x(j) <= u) = j;

end

% Evaluate spline and its three first derivatives.

s = u − x(k);

v = y(k) + s.*(d(k) + s.*(c(k) + s.*b(k)));

v1= d(k) +s.*(2*c(k)) + 3*s.*(b(k));

v2= 2+c(k)+6*s.*b(k);

v3= 6*b(k);

%−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−−
```

En command window:

```
>> x = [1 1.5 3 4.5 7 8.1 9.2 10]

x =

Columns 1 through 7

1.0000 1.5000 3.0000 4.5000 7.0000 8.1000 9.2000

Column 8

10.0000

>> y = [2 −3 4 6 2.3 4 −1 3 6 8]

y =
```

Columns 1 through 7

2.0000 −3.0000 4.0000 6.0000 2.3000 4.0000 −1.0000

Columns 8 through 10

3.0000 6.0000 8.0000

>> format short

>> x

x =

Columns 1 through 7

1.0000 1.5000 3.0000 4.5000 7.0000 8.1000 9.2000

Column 8

10.0000

>> u = 0.5:0.01:10.5;

>> [v,v1,v2,v3]=splinetx3(x,y,u)

>> [v,v1,v2,v3]=splinetx3(x,y,u);

>> plot(x,y,'r*',u,v2,'g',u,v3,'c')

>> plot(x,y,'r*',u,v,'r*',u,v1,'b',u,v2,'g',u,v3,'c')

Teniamos que tener el programa triidsolve:

function x = tridisolve(a,b,c,d)

% TRIDISOLVE Solve tridiagonal system of equations.

% x = TRIDISOLVE(a,b,c,d) solves the system of linear equations

% b(1)*x(1) + c(1)*x(2) = d(1),

% a(j−1)*x(j−1) + b(j)*x(j) + c(j)*x(j+1) = d(j), j = 2:n−1,

% a(n−1)*x(n−1) + b(n)*x(n) = d(n).

%

% The algorithm does not use pivoting, so the results might

% be inaccurate if abs(b) is much smaller than abs(a)+abs(c).

```
% More robust, but slower, alternatives with pivoting are:
% x = T\d where T = diag(a,−1) + diag(b,0) + diag(c,1)
% x = S\d where S = spdiags([[a; 0] b [0; c]],[−1 0 1],n,n)
x = d;
n = length(x);
for j = 1:n−1
mu = a(j)/b(j);
b(j+1) = b(j+1) − mu*c(j);
x(j+1) = x(j+1) − mu*x(j);
end
x(n) = x(n)/b(n);
for j = n−1:−1:1
x(j) = (x(j)−c(j)*x(j+1))/b(j);
end
```

cambiamos le valor de y:

```
>> y = [0 2 4 −1 −3 0 4 8 9 9];
>> u=0.9:0.01:10.1;
>> [v,v1,v2,v3] = splinetx3(x,y,u);
>> plot(x,y,'r*',u,v,'r*',u,v1,'b',u,v2,'g',u,v3,'c')
```

Mirar problem3.11

Mirar problem 3.9

18−ABRIL−06

<<Chapter 4>>

Teorema de los ceros de Bolzano.

*en matlab el poner ó es lo mismo que poner =.

En los apuntes:

Given a,b,f(a),f(b),e

while |b−a|>e|b|

x=a+b/2

if f(x) = 0 then

end

if f(x)f(a)<0 then

b=x

else

a=x

end

end

Hacemos un programa para hala ceros con el método de la bisección:

```
%este programa calcula los ceros
%de una función f(x) por el
%método de la bisección
%Inputs a,b,e
%a,b extremos del intervalo
%e error relativo admisible
% la función f(x) se escribe
%en un fichero auxiliar de nombre
%fun.m
function c = bisec(a,b,e)
fa = feval(`fun',a);
fb = feval(`fun',b);
while abs(b−a) > e*abs(b)
```

```
c = (a+b)/2;

fc = feval(`fun',c);

if fc == 0

break

end

if fc*fa < 0

b = c;

else

a = c;

end

end
```

y otro programa:

```
% este fichero sirve para almacenar la función

%f(x)

function y = fun(x)

y = sin(x.^2)−x.^3;
```

En matlab:

```
>> c = feval('fun',0)

c =

0

>> feval('fun',3)

ans =

−26.5879

>>>> sin(3^2)−3^3

ans =

−26.5879
```

```
>>>> feval('fun',8)

ans =

−511.0800

>> feval('fun',0.1)

ans =

0.0090

>> feval('fun',0)

ans =

0

>> c= bisec(0.1,3,10^−6)

c =

0.8960

>> format long

>> c= bisec(0.1,3,10^−6)

c =

0.89599368572235
```

Modificamos el primer programa:

```
%este programa calcula los ceros
%de una función f(x) por el
%método de la bisección
%Inputs a,b,e
%a,b extremos del intervalo
%e error relativo admisible
% la función f(x) se escribe
%en un fichero auxiliar de nombre
%fun.m
```

```
function [c,k] = bisec(a,b,e)

k=0;

fa = feval('fun',a);

fb = feval('fun',b);

while abs(b−a) > e*abs(b)

k = k+1;

c = (a+b)/2;

fc = feval('fun',c);

if fc == 0

break

end

if fc*fa < 0

b = c;

else

a = c;

end

end
```

modificamos también el segundo:

```
% este fichero sirve para almacenar la función

%f(x)

function y = fun(x)

y = x.^3 − 2.000001*x.^2+1.000002*x − 0.000001;

>> feval('fun',−10)

ans =

−1.210000121000000e+003

>> feval('fun',10)
```

```
ans =

8.099999190000000e+002

>> c = bisec(−10,10,10^−6)

c =

1.000000224848918e−006

>> u = −2:0.01:2;

>> v = feval('fun',u);

>> plot(u,v)

>> z= 0*u;

>> plot(u,v,u,z,'k')

Otro método es: EL MÉTODO DE NEWTON

Creamos el programa newton:

```
%Este programa obtiene los

%ceros de la función f(x)

% por el método de Newton

%Inputs: x0 (punto de partida),e (error relativo)

%Necesitamos dos ficheros auxiliares:

% − fun.m (donde guardamos la función f(x))

% − derfun.m (donde almacenamos la derivada

%f'(x) de la función f(x))

function [c,k] = newton(a,e)

k=0;

b=a;

fa=feval('fun',a);

dfa=feval('derfun',a);

c=a−fa/dfa;

while abs(c−b) > e*abs(b)

a=c;
```

b=a;

k = k+1;

fa = feval ('fun',a);

dfa=feval('derfun',a);

c= a−fa/dfa;

end

creamos el programa derfun:

%este fichero contiene la derivada de la función

%f(x) que esta guardada en el fichero fun.m

function dy = derfun(x)

%la otra función que usabamos era: dy = 2*cos (x.^2).*x−3*x.^2;

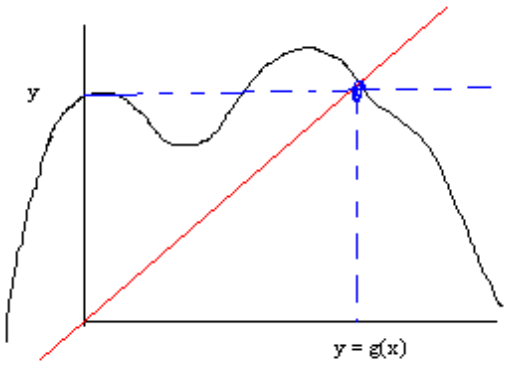
dy = 3*x^2−2*2.000001*x+1.000002;

20−abril−06

+página 10 del capítulo 5

Fix point method

(puntos fijos)



g(xo) = x1
g(x1)=x2
...
...
g(xn)= xn+1

xn--------->X*
n-->infi

lim xn = x
g(X*)= lim g(xn) = lim xn+1
= X*

(el lim tiende a infinito)

0 = f(x) =
g(x) - x

El algoritmo de punto fijo dice:

Dados x y e mientras que |g(x) −x | > |x|:

Given x

While |g(x) −x | > |x|

X g(x)

End

***** Creamos un programa llamado fijo.m: *******

%este programa calcula los puntos

%fijos de la función g(x)

% g(x*) = x*

% la función g(x) esta almacenada en el fichero fun.m

%inputs: dato inicio x0, error relativo (epsilon)

% outputs: punto fijo x*, numero de iteraciones k

function [x,k] = fijo(x0,e)

k = 0;

x= x0;

gx = feval('fun',x);

% en feval('fun',x); evalua g(x)

while abs(gx − x) > e*abs(x)

x = gx;

gx=feval('fun',x);

k = k+1;

end

y el programa:

function y = fun(x)

y = cos(x);

y ejecuto en matlab:

>> [x,k]=fijo (0,10^−6)

x =

0.7391

k =

35

Y con el programa derfun Nuevo:

%este fichero contiene la derivada de la función

%f(x) que esta guardada en el fichero fun.m

function dy = derfun(x)

%la otra función que usabamos era: dy = 2*cos (x.^2).*x−3*x.^2;

%dy = 3*x^2−2*2.000001*x+1.000002;

dy = −sin(x)−1;

en matlab:

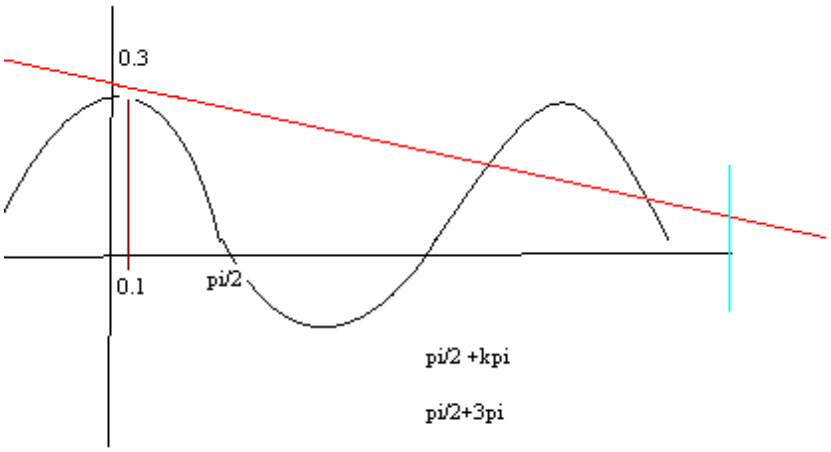
>> [x,k] = newton(0.1,10^−6)

x =

0.7391

k =

4



26−abril−06

+apuntes libro moler pagina zero página 20 en adelante

Con los programas:

derfun:

```
function dy = dfun(x)

% y = cos(x);

dy = 3*x^2−2 −5;
```

y:

fun:

```
function y = fun(x)

%y = cos(x)−x;

y = x.^3−2.*x−5;
```

En matlab:

```
>> u = 0:0.01:3;

>> v = fun(u);

>> z=0*u;

>> plot(u,v,u,z,'k');

>>

>> [c,k] = bisec(0,3,eps)

c =

2.0946

k =

53

>> [c,k] = newton(0,eps)

c =

2.0946

k =

19
```

```
>>
```

Donde bisec:

```
%Este programa calcula los ceros de una funcion f(x)
%por el metodo de la biseccion
%e error relativo admisible
%la funcion f(x) se escribe en un fichero auxiliar
%con el nombre fun.m
function [x,p] = bisec(a,b,e)
fa = feval('fun',a); %feval evalua la funcion en el punto dado
fb = feval('fun',b);
p = 0;
while abs(b−a) > e*abs(b)
p = p+1;
x = (a+b)/2;
fx = feval('fun',x);
if fx == 0
break
end
if fx*fa < 0
b = x;
else a = x;
end
end
```

Donde newton:

```
%Este programa obtiene los ceros de la funcion f(x)
%por el metodo de Newton
```

```
%x0 = punto de partida, e = error relativo
%necesitamos dos ficheros auxiliares
%fun.m(donde guardamos la funcion f(x)
%derfun.m(donde almacenamos la derivada
%f'(x) de la funcion f(x)
function [c,k] = newton(x,e)
k = 0;
b = x;
fx = feval('fun',x);
dfx = feval('derfun',x);
c = x − fx/dfx;
while abs(c−b) > e*abs(b);
x = c;
b = x;
k = k+1;
fx = feval('fun',x);
dfx = feval('derfun',x);
c = x−fx/dfx;
end
```

la nueva function derfun:

```
function dy = derfun(x)
% y = cos(x);
dy = 1./(1+x.^2);
>> [c,k] = newton(0,eps)
c =
1.7321
```

```
k =

6

>>
```

Ahora la funcion fun:

```
function y = fun(x)

y = sign(x−2).*sqrt(abs(x−2));

>> v = fun(u);

>> u = 0:0.01:4;

>> v = fun(u);

>> z=0*u;

>> plot(u,v,u,z,'k');
```

Ahora derfun:

```
function dy = derfun(x)

% y = cos(x);

%dy = 1./(1+x.^2);

dy = 1./(2*sqrt(abs(x−2)));

>> [c,k] = bisec(0,4,eps)

c =

2

k =

1

>>

>> v = fun(u);

>> u = 0:0.01:4;

>> v = fun(u);

>> z=0*u;
```

```
>> plot(u,v,u,z,'k');

>> [c,k] = bisec(0,4,eps)

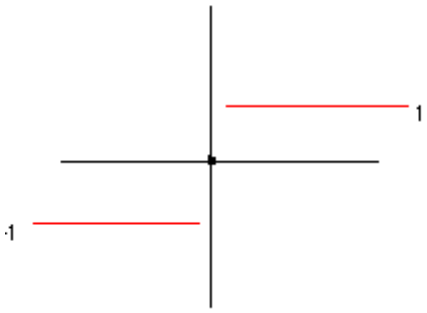
c =

2

k =

1

[c,k] = newton (0,eps)
```



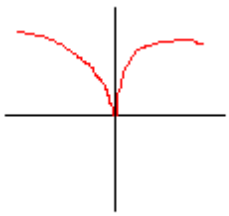
f(x) =
sign(x-2)raiz(abs(x-2))

f'(x)=
si x>a-> f(x) = raiz(x-a)
f '(x)= 1/(2*raiz(x-a))
si x <a f(x) = -raiz(a-x)
f ' (x)= -1/(2*raiz(z-x))
= 1/(2*raiz(a-x))

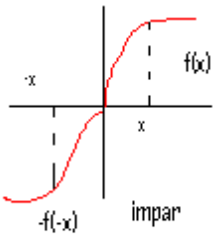
f ' (x) = 1/(2*raiz(abs(x-a))) x distinto de a

f(x) = feval ('fun',x)
f ' (x)

f(x) = f(-x) par
f(x) = -f(-x) impar



par



impar

```
>> u = −20:0.01:20;

>> v = besselj(0,u);

>> z=0*u;

>> plot(u,v,u,z,'k');

Warning: Imaginary parts of complex X and/or Y arguments ignored.
```

```
>>

>> u = 0:0.01:20;

>> v = besselj(0,u);

>> z=0*u;

>> plot(u,v,u,z,'k');

>> u = 0:0.01:40;

>> v = besselj(0,u);

>> z=0*u;

>> plot(u,v,u,z,'k');

>> u = −69:0.01:69;

>> v = besselj(0,u);

>> z=0*u;

>> plot(u,v,u,z,'k');
```

Cambio fun:

```
function y = fun(x)

%y = cos(x)−x;

%y = x.^3−2.*x−5;

%y = atan(x)−pi/3;

%y = sign(x−2).*sqrt(abs(x−2));

y = besselj(0,x);
```

y creo el problema 4 el programa:

```
% este pequeño programa (script)

%resuelve el problema 4.10

% del libro de mooler, buscamos

%los 10 primeros ceros de la función

% de Bessel de primera especie
```

```
%de orden 0, J_0(x),
%Para ello usamos el metodo de la bisección
%aplicado a los intervalos [1,4],
% [4,7],...,[29,32]
%Los intervalos los hemos obtenido
%por inspección representando graficamente
%la función.
x = [1 4 7 10 13 17 20 24 27 29 32];
c = zeros(10,1);
for n = 1:10
c(n) = bisec(x(n),x(n+1),eps)
end

Hacemos en matlab:

>> help svd

SVD Singular value decomposition.

[U,S,V] = SVD(X) produces a diagonal matrix S, of the same

dimension as X and with nonnegative diagonal elements in

decreasing order, and unitary matrices U and V so that

X = U*S*V'.

S = SVD(X) returns a vector containing the singular values.

[U,S,V] = SVD(X,0) produces the "economy size"

decomposition. If X is m−by−n with m > n, then only the

first n columns of U are computed and S is n−by−n.

For m <= n, SVD(X,0) is equivalent to SVD(X).

[U,S,V] = SVD(X,'econ') also produces the "economy size"

decomposition. If X is m−by−n with m >= n, then it is

equivalent to SVD(X,0). For m < n, only the first m columns

of V are computed and S is m−by−m.

Ejercicio 5.9

5.9. *Statistical Reference Datasets.* NIST, the National Institute of Standards and Technology, is the branch of the U.S. Department of Commerce responsible for setting national and international standards. NIST maintains Statistical Reference Datasets, StRD, for use in testing and certifying statistical soft− ware. The home page on the Web is [3]. Data sets for linear least squares are under \Linear Regression." This exercise involves two of the NIST reference

data sets.

² Norris. Linear polynomial for calibration of ozone monitors.

² Pontius. Quadratic polynomial for calibration of load cells.

For each of these data sets, follow the Web links labeled

² Data ¯le (ASCII Format)

² Certi¯ed Values

² Graphics

Download each ASCII ¯le. Extract the observations. Compute the polyno−

mial coe±cients. Compare the coe±cients with the certi¯ed values. Make

plots similar to the NIST plots of both the ¯t and the residuals.

Cogemos el ejercicio 5.10 del moler (y es el que entregamos de práctica)

5.10. *Filip data set.* One of the Statistical Reference Datasets from the NIST is the \Filip" dataset. The data consists of several dozen observations of a variable *y* at di®erent values of *x*. The task is to model *y* by a polynomial of degree 10 in *x*.

This dataset is controversial. A search of the Web for \¯lip strd" will ¯nd several dozen postings, including the original page at NIST [3]. Some math− ematical and statistical packages are able to reproduce the polynomial coef− ¯cients that NIST has decreed to be the \certi¯ed values." Other packages give warning or error messages that the problem is too badly conditioned to solve. A few packages give di®erent coe±cients without warning. The Web

o®ers several opinions about whether or not this is a reasonable problem. Let's see what MATLAB does with it.

The data set is available from the NIST Web site. There is one line for each data point. The data is given with the ¯rst number on the line a value of *y*, and the second number the corresponding *x*. The *x*−values are not monotonically ordered, but it is not necessary to sort them. Let *n* be the number of data points and *p* = 11 the number of polynomial coe±cients.

(a) As your ¯rst experiment, load the data into MATLAB, plot it with '.' as the line type, and then invoke the Basic Fitting tool available under the Tools menu on the ¯gure window. Select the 10th degree polynomial ¯t. You will be warned that the polynomial is badly conditioned, but ignore that for now. How do the computed coe±cients compare with the certi¯ed values on the NIST Web page? How does the plotted ¯t compare with the graphic on the NIST Web page? The basic ¯tting tool also displays the norm of the residuals, *krk*. Compare this with the NIST quantity \Residual Standard Deviation," which is

$$krk\,pn ¡ p$$

(b) Examine this data set more carefully by using six di®erent methods to compute the polynomial ¯t. Explain all the warning messages you receive during these computations.

² Poly¯t: Use polyfit(x,y,10)

² Backslash: Use X*n*y where *X* is the *n*−by−*p* truncated Vandermonde ma− trix with elements

$$Xi;j = xp¡j$$

$$i\ ;\ i = 1; : : : ; n;\ j = 1; : : : ; p$$

² Pseudoinverse: Use pinv(X)*y

² Normal equations: Use inv(X'*X)*X'*y.

² Centering: Let ¹ = mean(*x*); ¾ = std(*x*); *t* = (*x* ¡ ¹)=¾.

Use polyfit(t,y,10).

² Certi¯ed coe±cients: Obtain the coe±cients from the NIST Web page.

(c) What are the norms of the residuals for the ¯ts computed by the six di®erent methods?

(d) Which one of the six methods gives a very poor ¯t? (Perhaps the packages that are criticized on theWeb for reporting bad results are using this method.)

(e) Plot the ¯ve good ¯ts. Use dots, '.', at the data values and curves obtained by evaluating the polynomials at a few hundred points over the range of the *x*'s. The plot should look like ¯gure 5.5. There are ¯ve di®erent plots, but only two visually distinct ones. Which methods produce which plots?

(f) Why do poly¯t and backslash give di®erent results?

TEMA 6 del mooler:

Ejercicio 6.4:

6.4. Use quadtx with various tolerances to compute pi by approximating

pi = integral desde −1 a 1 de : 2/(1+x^2) dx

solución : 2*arcotg entre −1 y 1 = 2 [pi/4 − (−pi/4)] = pi

How do the accuracy and the function evaluation count vary with tolerance?

Una manera de calcular pi es por cuadraturas, pero no es muy eficiente.

F(x) = 2/(1+x^2)

Fname.m

Inline

En matlab:

>> F = inline('2./(1+x^2)')

F =

Inline function:

F(x) = 2./(1+x^2)

>> G = inline('x.^y','x','y')

G =

Inline function:

G(x,y) = x.^y

Con el programa quadtx:

function [Q,fcount] = quadtx(F,a,b,tol,varargin)

```
%QUADTX Evaluate definite integral numerically.
% Q = QUADTX(F,A,B) approximates the integral of F(x) from A to B
% to within a tolerance of 1.e−6. F is a string defining a function
% of a single variable, an inline function, a function handle, or a
% symbolic expression involving a single variable.
%
% Q = QUADTX(F,A,B,tol) uses the given tolerance instead of 1.e−6.
%
% Arguments beyond the first four, Q = QUADTX(F,a,b,tol,p1,p2,...),
% are passed on to the integrand, F(x,p1,p2,..).
%
% [Q,fcount] = QUADTX(F,...) also counts the number of evaluations
% of F(x).
%
% See also QUAD, QUADL, DBLQUAD, QUADGUI.
% Make F callable by feval.
if ischar(F) & exist(F)~=2
F = inline(F);
elseif isa(F,'sym')
F = inline(char(F));
end
% Default tolerance
if nargin < 4 | isempty(tol)

Ejercicio del libro moler (26 Chapter 5. Least Squares):

5.12. Planetary orbit [2]. The expression $z = ax2+bxy+cy2+dx+ey+f$ is known as a *quadratic form*. The set of points $(x; y)$ where $z = 0$ is a *conic section*. It can be an ellipse, a parabola, or a hyperbola, depending on the sign of the discriminant $b2 ¡ 4ac$. Circles and lines are special cases. The equation $z = 0$ can be normalized by dividing the quadratic form by any nonzero coe±cient. For example, if $f 6= 0$, we can divide all the other coe±cients by f and obtain a quadratic form with the constant term equal to one. You can use the Matlab meshgrid and contour functions to plot conic sections. Use meshgrid to create arrays X and Y. Evaluate the quadratic form to produce Z. Then use contour to plot the set of points where Z is zero.

```
[X,Y] = meshgrid(xmin:deltax:xmax,ymin:deltay:ymax);
Z = a*X.^2 + b*X.*Y + c*Y.^2 + d*X + e*Y + f;
contour(X,Y,Z,[0 0])
```

A planet follows an elliptical orbit. Here are ten observations of its position

in the (*x; y*) plane:

x = [1.02 .95 .87 .77 .67 .56 .44 .30 .16 .01]';

y = [0.39 .32 .27 .22 .18 .15 .13 .12 .13 .15]';

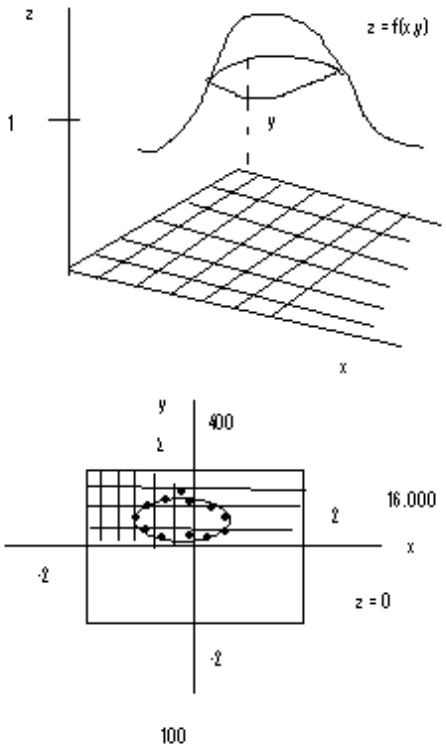
(a) Determine the coe±cients in the quadratic form that ¯ts this data in the least squares sense by setting one of the coe±cients equal to one and solving a 10−by−5 overdetermined system of linear equations for the other ¯ve coe±cients. Plot the orbit with *x* on the *x*−axis and *y* on the *y*−axis. Superimpose the ten data points on the plot.

(b) This least squares problem is nearly rank de¯cient. To see what e®ect this has on the solution, perturb the data slightly by adding to each coordinate of each data point a random number uniformly distributed in the interval [−.005,.005]. Compute the new coe±cients resulting from the perturbed data. Plot the new orbit on the same plot with the old orbit. Comment on your comparison of the sets of coe±cients and the orbits.

En matlab:

Practica3

```
[x,y]=meshgrid(−2:0.01:2,−2:0.01:2);
a=1;b=1;c=1;e=1;f=−1;
>> z = a*x.^2+b*x.*y+c*y.^2+b*x+e*y+f;
>> contour(x,y,z,[0 0])
>> contour(x,y,z,5)
>> contour(x,y,z,10)
```



Para cada punto de x e y tenemos una ecuación diferente de:

= ax^2 + bxy +cy^2+dx+ey

C= (a b c d e)' ; A*C = (1 . 1)' = r

X`2= (x1^2 . X10^2)'

A=[X`2 XY Y^2 X Y]

C = A/r

%ODE23TX Solve non−stiff differential equations. Textbook version of ODE23.

%

% ODE23TX(F,TSPAN,Y0) with TSPAN = [T0 TFINAL] integrates the system

% of differential equations y' = f(t,y) from t = T0 to t = TFINAL. The

% initial condition is y(T0) = Y0. The input argument F is the

% name of an M−file, or an inline function, or simply a character string,

% defining f(t,y). This function must have two input arguments, t and y,

% and must return a column vector of the derivatives, y'.

%

% With two output arguments, [T,Y] = ODE23TX(...) returns a column

% vector T and an array Y where Y(:,k) is the solution at T(k).

%
```

```
% With no output arguments, ODE23TX plots the emerging solution.
%
% ODE23TX(F,TSPAN,Y0,RTOL) uses the relative error tolerance RTOL
% instead of the default 1.e−3.
%
% ODE23TX(F,TSPAN,Y0,OPTS) where OPTS = ODESET('reltol',RTOL, ...
% 'abstol',ATOL,'outputfcn',@PLOTFUN) uses relative error RTOL instead
% of 1.e−3, absolute error ATOL instead of 1.e−6, and calls PLOTFUN
% instead of ODEPLOT after each successful step.
%
% More than four input arguments, ODE23TX(F,TSPAN,Y0,RTOL,P1,P2,...),
% are passed on to F, F(T,Y,P1,P2,...).
